Question 1

Suppose we use a hash function h to hash n distinct keys into an array T of length m . Assuming simple uniform hashing --- that is, with each key mapped independently and uniformly to a random bucket --- what is the expected number of keys that get mapped to the first bucket? More precisely, what is the expected cardinality of the set $\{k : h(k) = 1\}$.

Your Answer	Score	Explanation
<input type="radio"/> $1/m$		
<input type="radio"/> $m/(2n)$		
<input type="radio"/> $n/(2m)$		
<input type="radio"/> $1/n$		
<input type="radio"/> m/n		
<input checked="" type="radio"/> n/m	1.00	Use linearity of expectation, with one indicator variable for each key. The probability that one key hashes to the first bucket is $1/m$, and by linearity of expectation the total expected number of keys that hash to the first bucket is just n/m .
Total	1.00 / 1.00	

Question 2

You are given a binary tree (via a pointer to its root) with n nodes, which may or may not be a

binary search tree. How much time is necessary and sufficient to check whether or not the tree satisfies the search tree property?

Your Answer	Score	Explanation
<input checked="" type="radio"/> $\Theta(n)$	✓ 1.00	For the lower bound, if there is a violation of the search tree property, you might need to examine all of the nodes to find it (in the worst case).
<input type="radio"/> $\Theta(n \log n)$		
<input type="radio"/> $\Theta(\text{height})$		
<input type="radio"/> $\Theta(\log n)$		
Total	1.00 / 1.00	

Question 3

You are given a binary tree (via a pointer to its root) with n nodes. As in lecture, let $\text{size}(x)$ denote the number of nodes in the subtree rooted at the node x . How much time is necessary and sufficient to compute $\text{size}(x)$ for every node x of the tree?

Your Answer	Score	Explanation
<input checked="" type="radio"/> $\Theta(\text{height})$	✗ 0.00	How many distinct quantities are you responsible for computing?
<input type="radio"/> $\Theta(n^2)$		
<input type="radio"/> $\Theta(n)$		
<input type="radio"/> $\Theta(n \log n)$		
Total	0.00 / 1.00	

Question 4

Which of the following is *not* a property that you expect a well-designed hash function to have?

Your Answer	Score	Explanation
<input type="radio"/> The hash function should "spread out" most (i.e., "non-pathological") data sets (across the buckets/slots of the hash table).		
<input checked="" type="radio"/> The hash function should "spread out" every data set (across the buckets/slots of the hash table).	✓ 1.00	As discussed in lecture, unfortunately, there is no such hash function.
<input type="radio"/> The hash function should be easy to compute (constant time or close to it).		
<input type="radio"/> The hash function should be easy to store (constant space or close to it).		
Total	1.00 / 1.00	

Question 5

Suppose we relax the third invariant of red-black trees to the property that there are no *three* reds in a row. That is, if a node and its parent are both red, then both of its children must be black. Call these *relaxed* red-black trees. Which of the following statements is *not* true?

Your Answer	Score	Explanation
<input type="radio"/> There is a relaxed red-black tree that is not also a red-black tree.		
<input checked="" type="radio"/> Every binary search tree can be turned into a relaxed red-black tree (via some coloring of the nodes as black or red).	✓ 1.00	A chain with four nodes is a counterexample.
<input type="radio"/> Every red-black tree is also a relaxed red-black tree.		
<input type="radio"/> The height of every relaxed red-black tree with n nodes is $O(\log n)$.
